Continuous RVs in R

Built into R are some functions that work with the named continuous distributions. Recall we have the following types of functions:

For example:

- `dnorm(x, mu, sigma)` will evaluate the PDF of a $N(\mu, \sigma^2)$ distribution at the value `x`.
- `pnorm(q, mu, sigma)` will evaluate the CDF of a $N(\mu, \sigma^2)$ distribution at the value `q`
- `qnorm(p, mu, sigma)` will evaluate the inverse-CDF of a $N(\mu, \sigma^2)$ distribution at the value `p`
- `rnorm(n, mu, sigma)` will generate `n` random variables from the $N(\mu, \sigma^2)$ distribution

NOTE: for the `_norm()` functions in R, the functions expect standard deviation as input, not variance!!

```
# X ~ N(0, 4) -> What is P(X <= 0)?
pnorm(0, mean = 0, sd = 2)
```

```
[1] 0.5
```

The different distributions in R all follow the same format: `d<dist>()` or `p<dist>()`, and you specify the specific inputs and parameters.

```
# Generate 10 random variables from the Unif(0,1) distribution:
runif(10, min = 0, max = 1)
```

```
 [1] 0.06444214 0.31388489 0.39775415 0.78661485 0.62980994 0.60040826
 [7] 0.24917713 0.77357889 0.70789221 0.98193047
```

```
# X ~ Exp(2). What is f(1)?

# Obtain median of standard normal
```

Visualizing densities

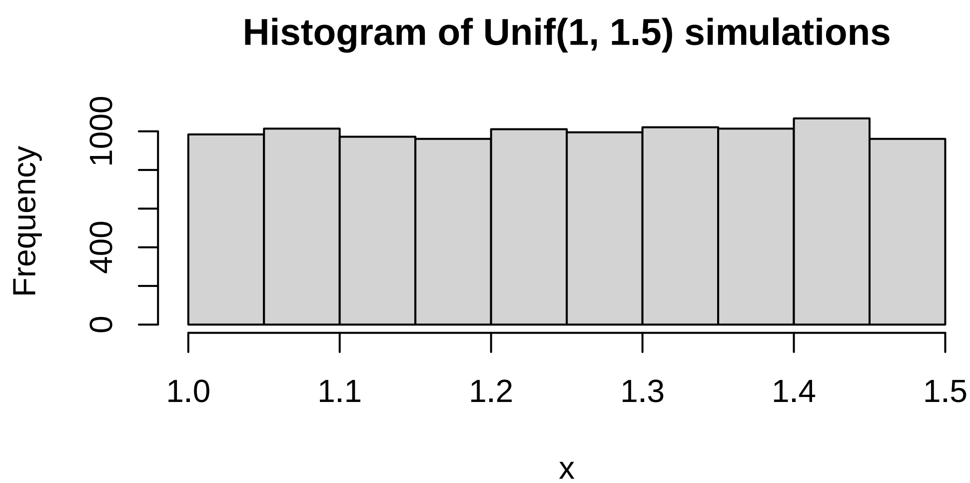
Sometimes it can be helpful to visualize the density of a distribution. There are a couple ways we can do this. Let's do this example for the $Unif(1, 1.5)$ distribution.

Option 1

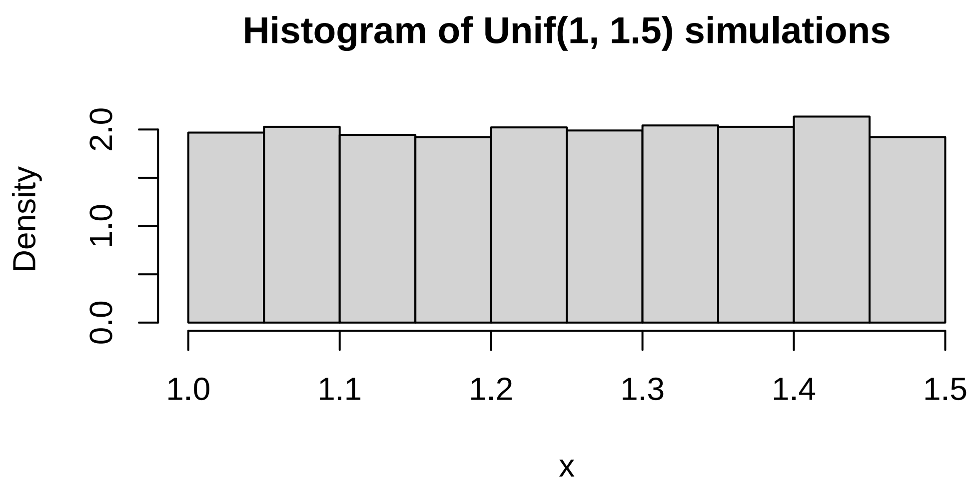
If we can randomly sample from the distribution, we can generate lots and lots of random variables from that distribution and make a histogram of them!

```
# simulate lots and lots of Unif(1, 1.5) rvs
sims <- runif(10000, min = 1, max = 1.5)

# make a histogram of the simulations
hist(x= sims, xlab = "x", main = "Histogram of Unif(1, 1.5) simulations")
```



```
# turn y-axis into a density
hist(x = sims,  xlab = "x", main = "Histogram of Unif(1, 1.5) simulations",
     freq = F)
```



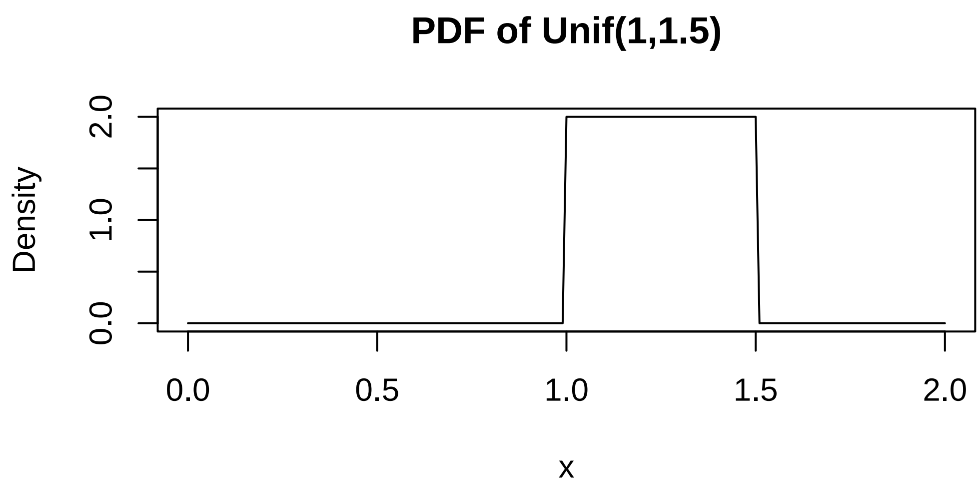
Option 2

If we have access to the PDF directly (which we do for the named distributions), we can simply graph the function

```
# create a sequence of values from 0 and 2 at equally-size 0.01 increments
x_seq <- seq(0, 2, 0.01)

# evaluate PDF of interest at each value in x_seq
f <- dunif(x_seq, min = 1, max = 1.5)

# type = "l" turns into lines
plot(x = x_seq, y = f, xlab = "x", ylab = "Density", main = "PDF of Unif(1,1.5)",
     type = "l")
```



Universality of Uniform / Probability Integral Transform

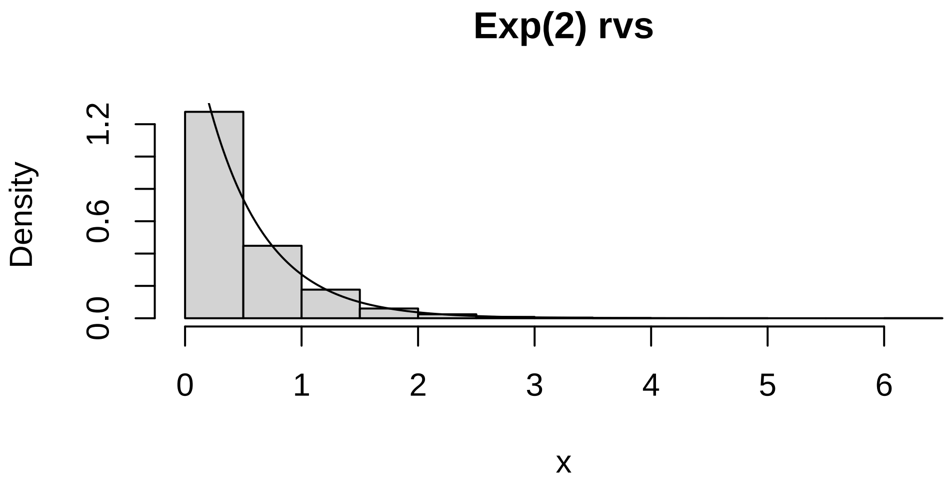
Now, let's see the University of the Uniform in action! Suppose you've lost access to all the functions in `R` that allow you randomly generate rvs from all the named distribution *except* for the Uniform. How can we simulate values from the Exp(2) distribution?

```
# generate lots of Unif(0,1) rvs
u <- runif(10000, min = 0, max = 1)

# use inverse CDF
lambda <- 2
x <- (-1/lambda) * log(1 - u)

# let's visualize them:
hist(x, xlab = "x", main = "Exp(2) rvs", freq = F)

# let's add the following to to double check
x_seq <- seq(0, 5, 0.01)
f <- dexp(x_seq, rate = lambda)
lines(x_seq, f, type = "l")
```



What if we didn't have access to the density function in R? No problem! We can make our own:

```
my_dexp <- function(x, lambda){
  n <- length(x)
  ret <- rep(0, n)
  for(i in 1:n){
      if(x[i] > 0){
        ret[i] <- x[i] * exp(-lambda * x[i])
      }
  }
}
f2 <- my_dexp(x_seq, lambda)
hist(x, xlab = "x", main = "Exp(2) rvs", freq = F)
lines(x_seq, f, type = "l")
```
